

Remote sensing in rangeland fire ecology: Comparing imagery to measured fire behavior, and burn severity across prescribed burns and wildfires

Response to review

AR: Author Responses (AR) appear below in this green text.

Reviewer 1

Just like last time, I still think this paper is worth publishing after major revision even though authors did not revise. To help you see exactly what needs fixing, I reorganized my comments as below.

AR: I appreciate the continued support for publication of this paper.

The assessment results of burn severity based on remote sensing data need to be verified using CBI-field data. However, authors did not mention this point. I believe this should be discussed in either Section 1.2 or the Discussion section.

AR: The absence of ground-truthed data for fires that occurred several years before has been explicitly acknowledged in the Discussion section.

In Section 2.3, only basic methods (i.e., Linear regression models) were employed. Some spatial statistical approaches could enhance the depth of this study.

AR: As there are no spatial components to the hypotheses, no spatial analyses were conducted. Linear regression is a perfectly acceptable method of analysis used at even the highest levels of research when linear patterns are hypothesized. Certainly, mixed-effect models and joint tests within interaction terms exceed “basic” linear regression.

I suggest combining the Results and Discussion sections into a single section (“Results and Discussion”).

AR: The AE indicated that this change should not be made.

In Results and Discussion sections, you need to use more words to explain results from mechanism view.

AR: Several additional paragraphs have been added to the Discussion to elaborate on underlying mechanisms.
